

POS for builders

A simple internal guide: what a POS is, what you must fill in, and what each POS can change.

- 1. POS for builders
- 2. Matching keys
- 3. Restaurant builders
- 4. Market builders
- 5. POS directory
- 6. How we work together

1. What is a POS?

This guide is for **people who build menus** in HAAT — Market builders and Restaurant builders. You do not need to know how the technical integration is built. You need to know **what to fill in**, so the customer’s order shows up correctly on the business’s own screen.

POS means the system the business already uses in the store.

- In a **restaurant**, it is the cash register / kitchen screen (for example Tabit).
- In a **market**, it is the system that holds products, barcodes, and prices (for example Comax).

The business does not want to keep two menus. So we connect HAAT to their POS. Then:

- 1. When someone orders on HAAT, the order appears on **their** screen.
- 2. Sometimes their prices, stock, or menu also update **our** menu.

A business is connected only if it has a **POS certificate** in HAAT (a record like “this shop uses Tabit”). If there is no certificate, treat it as a normal manual menu.

The three jobs a POS can do

Not every POS does all three.

Job	In simple words	Almost every POS?
Send them the order	Customer orders on HAAT → their kitchen / cashier sees it	Yes
Send us catalog info	They send us menu, prices, or stock. This is “the sync”	Only some
Read our catalog	They copy our menu. Only KubeGet does this	No

What you must get right

Restaurant builder

Pair every HAAT item with the POS item number (

PosId

). Tabit and McDonald's often do this pairing for you.

Market builder

Copy the

barcode

and

product code

exactly as they are in the POS file. There is no pairing table.

If the number is wrong, the customer can still order on HAAT — but the shop will see the wrong item, or “item not found.”

2. Matching keys

HAAT and the POS each have their own item numbers.

Example: they call a burger **#58821**. We call it **#4417**. Sync and orders only work if we know those two are the **same item**.

Restaurants = PosId

Think of **PosId** as “their item number,” saved next to our item in HAAT. Fill this in for meals, deals, toppings, and groups.

When a customer orders, HAAT **changes our numbers into their numbers**, then sends the order.

If a meal is live on HAAT with **no PosId**, the customer can buy it, and the kitchen will not know what it is. Map everything that can be ordered — including toppings.

Who fills in PosId?

POS	Who puts the number in?
Tabit or McDonald's (first full menu)	Automatic — created with the menu
EasySolution, BeecomCloud, LeenCopot	You , before go-live
Orders-only (Beecom, PayPo, PizzaHut, Iron, and similar)	You , from their item list
KubeGet	They do it on their side

Markets = barcode and product code

Markets have **no pairing table**. We find the product by the code written on it. Copy the value **exactly**. Do not drop a zero. Do not add a space.

Code you copy	Used for
Barcode	Finding the product (Comax, Aviv)
Product code	Finding the product (All4Shops, Barak) and attaching deals

Deals use **product code**, not barcode. If the product code on the deal does not match the file, the promotion will not work.

Who does the matching? We do — except KubeGet, who match on their side.

Before you finish a build

- ☐ The business has a POS certificate (it is really connected).
- ☐ You have their item list with **numbers**, not only names or a photo.
- ☐ Restaurants: every item that can be ordered has a PosId.

- ☐ Markets: barcode and product code match the file character by character.
- ☐ You placed a **test order** and the shop screen shows the same items.
- ☐ When they change items later, you update HAAT the same day.

3. Restaurant builders

Only Tabit and McDonald's can build the HAAT menu for you. For every other restaurant POS, you build the menu first, then you map PosId.

Your steps on every restaurant

1. **Is it connected?** Check there is a POS certificate. No certificate = treat it as a normal manual restaurant.
2. **Get their item list** with IDs, not only names.
3. **Build or check the HAAT menu** — same items, names, and prices.
4. **Fill PosId** on every meal, deal, topping, and group that can be ordered. Skip only if Tabit or McDonald's already created the mapping.
5. **Send a test order.** Wrong PosId is the usual reason an order "went to the POS wrong."
6. **Keep it updated** the same day they add or replace items.

Tabit

What it does: First time, builds the whole menu and fills PosId for you. If a menu already exists, only updates in stock / hidden. New items may arrive **hidden** for you to review. Can copy to franchise branches. Also sends order status.

What you do: Review the auto-built menu and hidden new items (they are not live until you review). Do not change PosId unless there is a duplicate, or the restaurant wants a HAAT-only item.

McDonald's

What it does: Creates and updates the menu and PosId mapping. Stock updates turn items available / unavailable.

What you do: Review the synced menu. If McDonald's marked something out of stock, do not unhide it by hand.

EasySolution

We call them on a schedule. They can hide/show items and update translations. They will **not** add a new dish.

What you do: Map everything before the first run. A new dish = you create it in HAAT and add PosId.

BeecommCloud and LeenCopot

We pull their item list so our copy stays fresh. This does **not** change the HAAT menu by itself.

What you do: Use that list when you map. New HAAT meals will not appear on their own.

KubeGet

Works backwards: they copy our menu and match items on their side.

What you do: Keep the HAAT menu clean. You do not have to map for them.

Orders only — you build everything

Beecomm, PayPo, NetLunch, Elpos, PizzaHut, Presto, Beteavon, Iron, Kaman

These do not update the catalog. You build the menu by hand and map every PosId before the first live order.

- PayPo and Beecomm send order status, but not menu updates.
- Presto gets the order as a file. Mapping work is the same for you.

Aviv restaurants: mapping + orders only. No product file for the restaurant menu. Aviv markets are covered in the market chapter.

Remember

- Only two POS types can build a restaurant menu: Tabit and McDonald's.
- Wrong kitchen ticket? Check PosId first. Names can look right while the number is wrong.
- Hidden Tabit items are waiting for you — they are not live yet.
- A missing dish may be a stock update. Check the POS type before you “fix” it.

4. Market builders

Markets use **barcode** and **product code**. There is no PosId table.

Most market POS types update products that already exist, and they create or update deals. They usually do not add brand-new products. The exception is **Comax**.

There is no safety net. One extra space or a missing zero on the barcode will not show a red error. The order simply will not match on their side.

Your steps on every market

1. **Which POS is it?** Comax, All4Shops, Aviv, Barak — or a fully manual catalog.
2. **Get their file** (CSV or JSON). Copy barcode and product code exactly.
3. **Build or align the HAAT catalog.** Do not invent extra product codes if this POS only updates existing products.
4. **Fill both codes.** Barcode finds the product for Comax and Aviv. Product code finds the product for All4Shops and Barak — and it is what deals use.
5. **Send a test order.**
6. **Keep it updated.** Aviv and Barak only refresh when their file is picked up — not instantly.

Comax

They can add new products, and update price and availability. We pull deals every day at 05:00 (and you can ask for an extra pull).

Match on: barcode or product code for products. Product code for deals.

What you do: Check codes on anything you add by hand. If a deal does not show, the product code does not match.

All4Shops

They send price and availability only. They cannot create a new product. We pull barcodes at 01:00 (mismatch email) and deals at 05:00.

Match on: product code for everything.

What you do: Create the HAAT product first. Then their price can land on it. Open the mismatch email — those rows will never update until you fix the product code.

Aviv

We download their CSV files. Product and deals: once a day. Price file: every 2 hours.

Match on: barcode for products. Product code for deals.

What you do: Build from their file. Prices are only as new as the last 2-hour file — not live.

Barak

We download their CSV. After we read a file, it is moved to an **OLD** folder so we do not read it twice.

Match on: product code (ItemCode).

What you do: HAAT ItemCode must match their file. If they say “we already sent the file,” it may already be in OLD. Ask for a new file, or a pull from backoffice.

Remember

- Copy codes exactly.
- Only Comax is expected to add new SKUs. All4Shops will never create a product for you.
- Deals use product code, even when the product itself matches on barcode.
- Aviv and Barak are not real-time.
- Read the All4Shops mismatch email.

5. POS directory

Look up a POS name and see what it can change on the menu.

Restaurants

POS	Can it build the HAAT menu?	What it can change	Who starts it	Code you must get right
Tabit	Yes (first time)	Full menu + hide / stock	They send it	PosId (automatic)
McDonald's	Yes	Full menu + stock	They send it	PosId (automatic)
EasySolution	No	Hide / show + translations	We pull on a schedule	PosId (you fill it)
BeecommCloud	No	Nothing on our menu. Refreshes their item list	We pull	PosId (you fill it)
LeenCopot	No	Nothing on our menu. Refreshes their item list	We pull	PosId (you fill it)
KubeGet	They copy our menu	—	They pull	They match on their side
Beecomm, PayPo, NetLunch, Elpos, PizzaHut, Presto, Beteavon, Iron, Kaman	No	Nothing. Orders only	—	PosId (you fill it)
Aviv (as restaurant)	No	Nothing. Orders only	—	PosId (you fill it)

Markets

POS	Can it add new products?	What it can change	Who starts it	Code you must get right
Comax	Yes	Products + deals	They send products. We pull deals	Barcode or product code. Deals = product code
All4Shops	No	Price, availability, barcodes, deals	They send prices. We pull the rest	Product code
Aviv	Updates what exists	Products, prices, deals	We download files	Barcode for products. Product code for deals
Barak	Updates what exists	Products + deals	We download files	Product code (ItemCode)

Something looks wrong?

You see this	Check this first
Wrong items on the shop screen	Restaurant Posld, or market barcode / product code
Old prices	Last Aviv / Barak file, or last Comax / All4Shops update
New dish never appears	Only Tabit and McDonald's can create restaurant meals
New market product never gets a price	All4Shops cannot create products — you must create it first
Deal not working	Deal matching uses product code
All4Shops row never updates	Mismatch email — product code does not match
Tabit item is hidden	New items can wait for your review
"We already sent the Barak file"	It may already be in their OLD folder

Aviv works as a market and as a restaurant. Unknown is not a real POS. MarketPrice is internal HAAT — do not describe it to partners.

6. How we work together

Sales / Account Manager owns the partner. They chase the client, book calls, and keep the process moving. Product and Content do not own that relationship.

Commercial (SE / AM)

- Talk to the partner and book meetings
- Make sure the client answers
- Set expectations on time and what is included

Content (builders)

- Collect the files (JSON or CSV) with real IDs
- Build the menu with the correct PosId (restaurants) or barcode / product code (markets)
- Update those values when the POS changes items
- Place a test order and confirm it works
- Help when an order fails; send real tech bugs to Product / R&D

Product / R&D

- Join after Commercial has checked the request is worth doing
- Size the work and decide a small first version vs full integration
- Technical kickoff; build or turn on the connection
- They do not replace Commercial as the partner contact

Before Product starts

Commercial answers: market or restaurant? How many shops? How many already on HAAT? Chain / franchise? Their own tech team?

After it is approved

1. Name the people (one POS contact, one HAAT contact).
2. Kickoff: what is in the first version, and the dates.
3. Content gets the catalog file with stable IDs.
4. Pilot shops go live. Success = test orders look correct on their screen.
5. After launch: order mistakes → Content first. Broken connection → Product / R&D.

You are done when

- ☐ The menu was built from their file, not from names only.
- ☐ PosId (restaurant) or barcode + product code (market) are filled.
- ☐ A test order shows the same items and prices on their POS.
- ☐ You know who to message when they change items after go-live.
